Introduction

The HD63B09EP microprocessor by Hitachi, is a MC68B09E compatible chip containing additional registers and an additional instruction set.

The 6309 was thought to be a flakey chip though, because it would sometimes crash or change the values of registers when it encountered an addressing mode or opcode invalid to the 6809. This was later found to be an extended instruction set and a feature that would trap some programming errors and jump to a specified location in memory.

Hitachi licensed the rights of the 6809 instruction set from

Motorola to make a 6809 compatible chip. When they finished the design, they found there was a lot of unused space in the chip. With this in mind they added extra registers and expanded on the instruction set, but due to the licensing agreement with Motorola, they were unable to release the information about the extra features.

Not only did the chip have an expanded instruction set, but it also had a native mode that would run many of the instructions in fewer clock cycles and a mode select for the FIRQ (Fast Interrupt ReQuest) that would enable it to operate the same as the IRQ.

In fact, all new instructions will execute in emulation mode, which was originally seen when 'illegal' 6809 instructions produced odd results when run on a computer with a 6309 installed.

The additional instruction set was first written about in the April 1988 issue of "Oh!FM", a Japanese magazine, and was later brought to the attention of the 6809 community by Hirotsugu Kakagawa. He followed up a series of '6809-6309 differences' messages on comp.sys.m6809 by posting a detailed explanation of the new features and instructions of the 6309. This opened a whole new door to those who wished to use the 6309 in place of the 6809.

The information in this reference is of technical nature and makes no attempt to teach assembly language programming. It is ONLY a technical reference guide for those who already know assembly and wish to use these features in their programs. Although all of the opcodes for the 6309/6809 chip are listed in the appendix, only the additional features supplied by the 6309 will be discussed in detail.

Summary of Features

More registers:

- one 8/16 bit 'zero' register
- Two 8bit accumulators.
- One 16bit concatenated register
- One 16bit value register.
- One 8bit mode/error register.
- One 32bit concatenated register

Two modes: MC68B09E emulation mode and HD63B09EP native mode.

Reduced execution cycles when running in native mode.

Many additional instructions.

Error trapping of illegal instructions and zero divisions.

HD63B09EP Technical Reference Guide
Page 2

Description of Additional Registers

The 6309 has 7 additional registers. Only 4 of these are actual registers. 2 are combinations of registers, and the last is a constant-value register. These registers are:

ACCE	- 8 bit accumulator.
ACCF	- 8 bit accumulator.
W	- 16 bit concatenated register (ACCE and ACCF combined).
Q	- 32 bit concatenated register (ACCA, ACCB, ACCE and ACCF combined).
V	- 16 bit register (which can only be accessed with the inter-register instructions).
0	- zero register
MD	- 8 bit mode/error register.

ACCE and ACCF both work in much the same manner as the ACCA and ACCB accumulators. This makes for easier programming in math and data oriented routines.

The W register is like the D register in the 6809. It is a concatenated register containing the values of ACCE and ACCF as one 16 bit

value. ACCE is contained in the high 8 bits and ACCF is contained in the low 8 bits.

The Q register is a 32 bit concatenated register. This register is composed of the concatenation of D and W, which in turn are composed of the registers ACCA, ACCB, ACCE and ACCF respectively. This register is used mostly with the additional math instructions supplied with the 6309 which will be discussed later.

The V register is a 16 bit register that can only be accessed with inter-register instructions such as TFR and EXG. The contents of this register will not change if the CPU is reset, allowing this register to be used as a constant value for the program.

The 0 register is always zero, independent of writes to it.

It enables a zero value to be used in inter-register operations without accessing memory, or changing the value of another register.

The MD register is a mode and error register and works much in the same way as the CC register. The bit definitions are as follows:

Write bits

Bit 0 - Execution mode of the 6309.
If clear (0), the cpu is in 6809 emulation mode.
If set (1), the cpu is in 6309 native mode.

Bit 1 - FIRQ mode
If clear (0), the FIRQ will occur normally.
If set (1), the FIRQ will operate the same as the

IRQ

Bits 2 to 5 are unused

Read bits - One of these bits is set when the 6309 traps an error

Bit 6 - This bit is set (1) if an illegal instruction is

encountered
Bit 7 - This bit is set (1) if a zero division occurs.

HD63B09EP Technical Reference Guide
Page 3

Modes of Operation

The 6309 has two modes of operation; 6809 Emulation mode in which

the chip acts and executes instructions the same as the 6809, and 6309

Native mode which stores an extra two bytes on the stack when an interrupt

(IRQ) occurs, and executes instructions in fewer clock cycles.

When in native mode, the W register (2 additional bytes) is stored

(PSHS) on the system stack when an interrupt occurs, it is stored on the

stack right after the D (general data) register. Since ALL register

values are stored on the system stack when an IRQ (NOT FIRQ - See FIRQ

modes for more information) occurs, great care should be taken when

writing or patching those routines to run in native mode.

Pull <- CC,A,B,E*,F*,DP,Xhi,Xlo,Yhi,Ylo,Uhi,Ulo,PChi,PClo <-
Push

* indicates the additional registers stored on the system stack

When in native mode those interrupt routines which modify the return

address by modifying the 10th and 11th byte offsets from the stack (STX

10,S or STY 10,S etc.) will have to be changed to modify the

12th and 13th
byte offsets from the stack (STX 12,S or STY 12,S etc.). If those routines are not patched to run in native mode they will either get stuck in a continuous loop or will crash the system due to the fact that they are not returning to the correct address. This poses a MAJOR problem for OS-9 Level II since its main interrupt handling routine relies highly on the changing of the return (PC) address on the stack. Disk read/write and formatting routines also rely heavily on changing the return address during an NMI (Non-Maskable Interrupt).

To patch those routines which do modify the return address, the program or routine must be disassembled or modified with a disk sector editing program. Look for instructions such as STX 10,S or STY 10,S that has an RTI (Return from Interrupt) instruction within the next few lines of the routine. The line containing STX 10,S or STY 10,S should be changed to STX 12,S or STY 12,S respectively.

Remember, after those routines are patched, those programs using them will NOT work in emulation mode and will require native mode to be enabled upon startup.

Native Mode and Timing Loops

There is at least one more problem that needs to be addressed. Those are routines which are dependant on timing loops for accurate operation. Since the 6309 executes instructions faster when in native mode, those routines that use timing loops would be effected. Since this can pose a problem and can create erratic operation, the delay value or routine will need to be changed for the routine to operate correctly.

Those routines are usually serial-printer routines, cassette read/write timing routines, software clocks and some disk read/write routines.

HD63B09EP Technical Reference Guide
Page 4

Modes of the Fast Interrupt Request (FIRQ)

The designers of the 6309 decided that with the additional instructions and native mode of operation, the FIRQ may be used more than it usually is. With this in mind they decided to allow you to make the FIRQ run the same as the IRQ and store (PSHS) all the current values of the registers on the system stack. Normally, the FIRQ only stores the CC (condition code) and the PC (Program Counter/return address) on the stack, so to keep compatability with the 6809, they included it as a selectable feature in the MD (Mode/status) register.

Inter-Register Instructions

The new Inter-Register instructions (ADCR, ADDR, CMPR, EORR, ORR, SBCR, and SUBR) all work the same as their register/memory (ADCA, ADDA, etc.) counterparts except that they operate between registers. All of the new instructions use the same post-byte information as the normal TFR instruction and use the format of R0,R1 (register 0 and Register 1 respectively) with the result going into R1. See Block Transfers for information on the TFR block move instructions.

Mixed-size inter-register operations default to using identical sized register. So TFR A,X actually executes as TFR D,X.

You could also do 'lea(d) d,pc' calculations by doing 'addr pc,d'. As

the new inter-register instructions can now perform math using the PC

register, REALLY odd possibilities exist. Try looking at code like

'eorr d,pc', and figuring out where it ends up.

Inter-register instructions with 16-bit r1 and CC or DP (8-bit r2)

are legal, but the results are unknown.

Bit Manipulation of Memory Locations

The AIM, EIM, OIM and TIM instructions all do logical bit

manipulations to locations in memory, with the result stored into the

location, and the respective bits for each instruction set in the CC

register. They can be used in the DIRECT, INDEXED or EXTENDED addressing

modes.

Instruction descriptions:

AIM - AND IN MEMORY

EIM - EOR IN MEMORY

OIM - OR IN MEMORY

TIM - TEST bits IN MEMORY

Instruction format: X, post byte, operand

Where X is the instruction op-code, post-byte contains the bits to

AND, OR, EOR or TEST against the memory location, and the operand is the

memory location or indexing post-byte depending on the mode of operation.

Mnemonic format:

Instruction logical operation value, memory location or index operation

Mnemonic example:

AIM #\$0F,\$E00

The example takes the contents of memory location \$E00, does a LOGICAL and with the Value #\$0F and then stores the result back into \$E00.

HD63B09EP Technical Reference Guide
Page 5

Bit Transfers Between Memory Locations and Registers

The BAND, BIAN, BOR, BIOR, BEOR, BIEOR, LDBT, and STBT all do logical operations to bits for the n-th bit in a memory location and the m-th bit of a register. The LDBT and STBT instructions allow you to transfer certain bits between registers and memory locations. All instructions allow you to specify which register to use, which bit location to use in the register, which bit location to use in the memory location, and the memory location to use. This allows you to transfer/or do a logical operation with the 7th bit of a register and the 3rd bit of a memory location. All bits are accessible on either the register or memory locations. The only limitations are that the instructions can only be used with the A and B accumulators and the CC (condition Code) registers. It should also be noted that these instructions can only be used in the DIRECT addressing mode.

Instruction description:

BAND - AND a bit in a register with bit from memory location
BIAND - AND a bit in a register with the complement of the bit in memory
BOR - OR a bit in a register with a bit from a memory

location

BIOR - OR a bit in a register with the complement of the bit in memory

BEOR - EOR a bit in a register with a bit from a memory location

BIEOR - EOR a bit in a register with the complement of the bit in memory

LDBT - Load a bit from a memory location into a bit in a register

STBT - Store a bit from a register into a memory location.

Instruction format:

x, post-byte, memory location

Where X is the instruction op-code, the post-byte contains the

register, source and destination bit information and the memory location

is the 8 bit value of the memory location to be used

(Remember only DIRECT

mode is allowed with these instructions).

Mnemonic format:

instruction, register, source bit, destination bit, memory location

Mnemonic example:

BOR A,1,7,\$00

The example would take the first (1) bit of register A (A) and OR it

into the 7th (7) bit of memory location \$00 (\$00) of the direct page (DP register value)

The post-byte of these instructions are not the same as the post-byte

used in any other operation (indexed or inter-register) as all of the

information (register, source and destination bit) is contained in one post-byte value.

Block Transfers

Block transfers are used to move a certain number of bytes from one place in memory to another with the use of one instruction. Two 16 bit registers (X, Y, U or S) are used to specify the source and destination addresses, and the size of the block to be transferred is specified with the W register. It should be noted that even though the IRQ and FIRQ only occur after the current instruction is finished, block moves can be interrupted. After the interrupt returns, the last byte read is read once more. i.e. It is read twice by the CPU. This can cause problems with memory mapped I/O devices, so caution is advised when using the block transfers. There isn't much control over these 4 instructions so the only thing applicable for them would be large block moves such as scrolling the screen or clearing an area in memory with a certain value.

TFM r0+,r1 and TFM r0,r1+ can be considered a poor mans DMA channel.

Since all the data is either copied into or read from one memory location.

Four types of block transfers have been provided.

Mnemonic examples:

(R0 - source address register, R1 - destination address register.)

TFM r0+,r1+

- Transfer from R0 to R1 in incrementing order.

TFM r0-,r1-

- Transfer from R0 to R1 in decrementing order.

TFM r0+,r1
- Pour from R0 into R1, only incrementing R0 (R1 stays the same).

TFM r0,r1+
- Read from R0 into R1, only incrementing R0 (R1 stays the same).

Mnemonic example:

```
LDW #$100
LDX #$600
LDY #$700
TFM X+,Y+
```

The example would move 256 (LDW #\$0100) bytes from #\$600 (LDX #\$0600) in memory to #\$700 (LDY #\$0700) in memory, incrementing the value of each register (X and Y), and decrementing the value of the W register each time a byte is moved.

When moves like this are done, the pointer registers (X and Y in the example) will not be the same value they were before the transfer was initiated, but will be their original values PLUS the value of the W register (\$100 in the example). So in the example once the move is complete, the value of X will be returned as \$700 and the value of Y will be returned as \$800. The value of W register will be 0.

It is illegal to use any of the CC, DP, W, V, 0, or PC registers as either a source or destination register. Note that the D register CAN be used with the TFM instructions.

New math commands

The 6309 has 3 additional math instructions. A 16 bit by 16 bit signed multiply (MULD), a 16 bit by 8 bit signed divide (DIVD) and a 32 bit by 16 bit signed divide (DIVQ). These instructions can all be used in Immediate, direct, indexed and extended addressing modes.

The MULD (16 bit by 16 bit) instruction does a signed multiply of the contents of the D register and a value from memory (or in direct mode). The signed result is stored in the Q register.

The DIVD (16 bit by 8 bit) instruction does a signed divide of the contents of the D register with a value from memory (or in direct mode). The signed result is stored with the quotient in W and the modulo (remainder) in D.

The DIVQ (32 bit by 16 bit) instruction does a signed divide of the contents of the Q register with a value from memory (or in direct mode). The signed result is stored with the quotient in W and the modulo (remainder) in D.

Error Trapping

The 6309 has an internal error trapping handler that will jump to a specific location in memory when either an error is encountered in the DIVision instructions (only divide by zero) or an illegal instruction is encountered. When an error is encountered, the 6309 will jump to the memory location contained in \$FFF0 (and \$FFF1) which was originally reserved by the 6809.

The trap may cause problems with machines that have \$FF00 hardcoded

with the values \$0000. A new EPROM should be burned to correct for the new behaviour of the 6309.

As many people know, an illegal instruction trap is extremely useful for debugging programs, as it prevents the entire machine from crashing when a bug is encountered.

Note that many pseudo-legal instructions on the 6809 are now illegal on the 6309, e.g. \$1020xxxx executes as an LBRA on a 6809, but results in a trap on a 6309.

Additional Instructions

The 6309 has MANY new instructions. Most are variations of old instructions of the 6809 for use with the new registers. The new instruction set can be used in both native and emulation mode. Here is a list of the new instructions of the 6309:

ADCD

- Adds immediate or memory operand to the D register plus the current status of the carry with the result going to D.

ADCR

- Adds two registers together plus the current status of the carry.

HD63B09EP Technical Reference Guide

Page 8

ADDE , ADDF, ADDW

- Add of immediate or memory operand to E, F or W with results going to E, F or W

ADDR

- Adds two registers together

ANDD

with - Logical AND of immediate or memory operand to D register
result going to D.

ANDR

- Logical AND of a register with the contents of another register

ASLD (Same as LSLD)

LSB. - Arithmetic shift left. Shifts D one bit left, clearing

ASRD

- Arithmetic shift right of the D register with sign extending.

BITD

- Test any bit or bits of the D register.

BITMD

- Test any bit or bits of the MD (mode) register.

CLRD, CLRE, CLRF, CLRW

- Clear register D, E, F or W to zero.

CMPE, CMPF, CMPW

memory - Compares the contents of E, F or W with the immediate or
operand. Sets all CC except H on result.

CMPR

except H on - Compares one register to another and sets all CC bits
result.

COMD, COME, COMF, COMW

one's and - One's complement D, E, F, or W. Changes all zero's to
all one's to zero's.

DECD, DECE, DECF, DECW

- Decrement D, E, F, or W by 1.

DIVD, DIVQ

(DIVQ) signed - Does a 16 bit by 8 bit (DIVD) or a 32 bit by 16 bit
divide with immediate or memory operand with quotient in
W and modulo
(remainder) in D.

EORD

- Logical exclusive OR of D and immediate or memory operand.

EORR

- Logical exclusive OR of one register with the value of another register.

INCD, INCE, INCF, INCW

- Increment D, E, F or W by 1.

LDE, LDF, LDQ, LDW, LDMD

- Standard loading of E, F, Q, W or MD with immediate data value or operand from memory. (LDMD only valid with IMMEDIATE mode)

HD63B09EP Technical Reference Guide

Page 9

LSLD (Same as ASLD)

- Logical shift left. Shifts D one bit left, clearing LSB.

LSRD, LSRW

- Logical shift right. Shifts D or W one bit right, clearing MSB.

MULD

- Performs as 16bit by 16bit signed multiply with immediate or operand from memory. Result stored in Q.

NEGD

- Two's complement D register.

ORD

- Logical OR of register D and immediate or memory operand.

ORR

- Logical OR of one register with another.

PSHSW, PSHUW

- Stores contents of the W register on the (system or user) stack.

PULSW, PULUW

- Pull value from (system or user) stack into register W.

ROLW, ROLD

- Rotate D or W one bit left through the Carry Condition code.

RORD, RORW

- Rotate D or W one bit right through the Carry Condition code.

SBCD

- Subtract an immediate or memory operand plus any borrow in Carry from contents of D. Result stored in D.

SBCR

- Subtract the value of one register from another plus any borrow in the CC carry.

SEXW

- sign extend the W register into the D register.

STE, STF, STQ, STW

- Store register E, F, Q or W to memory location (E,F), two memory locations(W), or four memory locations (Q).

SUBE, SUBF, SUBW

- Subtract immediate or memory operand from E, F or W. Result stored back in same register.

SUBR

- Subtract the value of one register from another.

TFM (Block transfer)

- Transfer W number of bytes from one location to another. Returns pointer registers offset of the starting value in the W register and returns the W register as 0. Indexed operation only

TSTD, TSTE, TSTF, TSTW

- Test contents of D, E, F or W by setting N and X condition codes based on data in register.

Opcode and Mnemonics Reference Table
Page 10

The Opcode and Mnemonics opcode reference tables are

both complete listings that contain both the Opcode instruction and the HEX equivalent in all available addressing modes. The first table is arranged sequentially by the binary opcodes, while the second table is arranged alphabetically by the Mnemonic instructions.

At the end of the second table there are data tables containing information on Bit transfer/manipulation, branch instructions, inter-register instructions, and general register and stack information. These are all helpful to the serious assembly language programmer, who should always have one.

Register Descriptions

X	- 16 bit index register
Y	- 16 bit index register
U	- 16 bit user-stack pointer
S	- 16 bit system-stack pointer
PC	- 16 bit program counter register
*V	- 16 bit variable register (inter-register instructions only)

|*0 - 8/16 bit zero register (inter-register instructions only)

* Indicates new registers in 6309 CPU.

Push/Pull Order of Stack

		Condition Code Register							

			E		F		H		I
			N		Z		V		C

_____	Entire flag	_____							
_____	Carry flag								
_____	FIRQ mask	_____							
_____	Overflow								
_____	Half carry	_____							
_____	Zero								
_____	IRQ mask	_____							
_____	Negative								

The PSH(s,u) and PUL(s,u) instructions require one additional cycle for each byte pushed or pulled.

Alan DeKok's addition to the above...

The new features of the 6309 are closely related to the changes in design from the 6809. The 6309 is micro-coded, which allowed the designers to easily add new instructions and registers. It also has a one byte pre-fetch 'cache', which enables the 6309 to execute instructions like 'lsld' (2-bytes) in one clock cycle. The design of the 6809 series allows them to read one byte per clock cycle MAXIMUM, but there is a catch. Most instructions take more clock cycles to execute

than
bytes they contain. While the 6309 is performing internal
calculations, the 'cache' hardware goes and reads the next
instruction
byte, leaving only one additional byte to be read to execute the
'lsld'.
Reading this byte requires one clock cycle, and then the
instruction
is executed while the CPU fetches the next instruction.

The 6309 has a true 16-bit internal design.
e.g. the EXG instruction operates as

```
6809: read op-code
      read inter-register byte (r0,r1)
      r0_high -> temp_high
      r0_low  -> temp_low
      r1_high -> r0_high
      r1_low  -> r0_low
      r0_high -> r1_high
      r0_low  -> r1_low
```

8 actions, 8 clock cycles.

```
6809: read op-code
      read inter-register byte (r0,r1)
      r0 -> temp
      r1 -> r0
      r0 -> r1
```

5 actions, 5 clock cycles.

The 6309 native mode instruction execution clock lengths can be
mostly accounted
for by accounting for the pre-fetch cache and the internal 16-bit
ALU.

TFM has some caveats. TFM r1-,r2- should NOT be used to setup
the
stack, as it's a POST-decrement instruction, not PRE-decrement.

Watch out for TFM r1,r2+ if you're reading from a peripheral.
Why? The TFM uses the 1-byte 'cache' as an internal buffer for
the
byte that it's currently moving. The TFM instruction is
interruptible
(the only instruction that is), and code execution during the
interrupt will destroy the byte in the cache.

On returning from the interrupt, the TFM will read the FROM
address again to get the lost byte, which may be the wrong one.

The visible effect of this is that block moves sometimes have a byte missing from the middle, and everything after that byte shifted down one address.

There are a few ways of checking if you're running on a 6309 or a 6809, these include:

```
:
tfr 0,d  -> illegal registers are '$FFFF' on a 6809, $0000 on a
6309
tstb     ->
beq  Is6309
:

:
ldb #$ff
clrd     -> executes as a $10 (ignored) $4F (clra) on a 6809
tstb
beq  Is6309
:
```

It's a bit harder to check if the system is running in native mode or not. Most of the time it won't be necessary, but the only really method is to do:

```
:
pshs cc,d,dp,x,y,u  SAVE ALL REGISTERS AS CHECKING WILL TRASH
THEM
leax Is6309,pc
pshs x               save address of 6309 flag code
leax Is6809,pc
pshs x               save address of 6809 flag code
pshs cc,d,dp,x,y,u  save registers
orcc #ENTIRE         set to ALL registers on-stack
rti                  go to 6309/6809 code
```

```
Is6309 clr <Flag     it's a 6309
bra Continue
```

```
Is6809 leas 2,s      account for 6309 PC
lda #$FF
sta <Flag
```

```
Continue puls cc,d,dp,x,y,u  restore all registers
[etc...]
:
```

Note that the checks for both 6809/6309 and native/emulation

will execute
perfectly on both 6809 and 6309 systems, and will give the correct
results
in all cases.

In order to check for 6309 FIRQ operation (i.e. all registers
saved),
you'd have to do something like

```
[ enable FIRQ's ]
:
  leau -3,s      where stack will be if only CC and PC are saved
  stu <test      remember the pointer
loop tst <check  FIRQ happened yet?
  bne loop       no, wait for an FIRQ
[...]
```

```
FIRQ cmps <test  only CC, PC saved?
  bne Is6309F    no, it's 6309 FIRQ mode
  clr <F.Flag    set to 6809 IRQ mode
  bra continue
```

```
Is6309F lda #$FF don't bother saving A as 6309 FIRQ mode already
saves it
  sta <F.Flag    set the FIRQ flag
```

```
continue clr <check      we've done an FIRQ, so we can exit
  rti
:
```

The W,E, and F registers do not have the full immediate
addressing
mode capabilities that D,A, and B do. SBC, AND, BIT, EOR, ADC, OR
with E,F,W are available only in register-register mode. LSR,
ROR,
ROL are available for W but not for E,F. ASR, ASL, LSL, NEG do
not
exist at all for W,E,F.

ASL can sort of be implemented by doing a ADDR R1,R1. (see
later)

You can also do things like 'leax u,x' by doing a ADDR u,x.

Sadly, many of the new 6309 instructions are useless in everyday
life. The bit manipulation instructions are interesting, but slow
and
mostly of limited value. Same with much of the DIV/MUL higher
math. The
AIM, etc. are very useful, though.

Programmer recommendations

Try to stay away from using the W register. It's got another pre-byte (like instructions using 'Y' or 'S'), and is correspondingly larger and slower. E and F are best used mainly instead of pushing loop counters onto the stack when you're running out of registers.

The V register is mostly pointless. If you're doing context switches, it isn't saved across interrupts unless you do so manually. Shuffling data back and forth between other registers and V is a lot of trouble. Any math, etc. involving V is generally done much faster using a real register. After going through 1meg+ of 6309 assembly code which is everything from an OS kernel to serial drivers to graphics drivers, I've never seen a use for the V register.

Of course, you could put '\$FFFF' into V, and have registers for reg-reg addressing modes with bits all zero (0), and another with bits all 1 (V).

Pseudo-nops: `tfr 0,0; exg 0,0`

Extremely small software timing loops with large delays may be generated by performing a 'LDW', and then 'TFM r0,r0+'.

Many programs can be executed in 6309 native mode by patching only the IRQ code, if it accesses the stack. A 'LDMD #\$01' may be performed as soon as your program starts executing, and will see an immediate 10-15% speed increase. Software timing loops must be checked!

Opcodes Hitachi left out of the 6309: and some round-about equivalents
